

Percent of products within each store by predicted NOVA classification.

I wanted to compare food processing levels across Whole Foods, Walmart, and Target. Whole Foods is often associated with higher-quality or less processed food, so I wanted to see whether that pattern appears in the dataset. The result shows that Whole Foods has fewer ultra-processed products than the other two stores, although they still make up 67% of its selection.

I used a 100% stacked horizontal bar chart so the processing-level proportions can be compared directly across stores. The blue shades become darker as the NOVA processing level increases, and the ultra-processed percentages are labeled directly because they are the main takeaway.

I grouped products by store and FPro_class, then converted the counts to percentages within each store. During development, I tested several nutrition-related ideas before choosing this comparison because it produced a clearer and more interpretable pattern.
